The importance and challenge of modeling irrigation-induced erosion

R.E. Sojka, D.L. Bjorneberg, T.J. Trout, T.S. Strelkoff, and M.A. Nearing

Abstract: Irrigation-induced erosion and rain-induced erosion result from very different systematics. Therefore, both cannot be predicted effectively using the same models. The average two-fold yield and three-fold economic advantage of irrigation over rain-fed agriculture, coupled with the fragility of irrigated land and the strategic importance of irrigation development to meet world agricultural production needs, has raised the urgency for the

675 M ac Irrigated Worldwide

80-90% Surface Irrigated
Half (?) Furrow Irrigated

Irrigation's Global Importance

Total Cropland 3-3.5 B ac
-Irrigated Ag. 0.68 B ac

- 💧 **1/3 of all of earth's harvested crops on 1/6 of the earth's croplands**
- 💧 **1/2 of the value of all crops harvested on 1/6 of the earth's croplands**
- 💧 **1/3 earth's harvested food grown on 125 M ac (1/30 area)**

U.S. Irrigated Agriculture

2002 Census of Agriculture

- ◆ 303 M ac of TOTAL harvested crop land
- ◆ 55 M ac of IRRIGATED crop land
- ◆ \$95 B TOTAL market value of crops sold
- ◆ \$57 B market value of IRRIGATED crops sold
- ◆ >80% of U.S. fresh fruit and vegetables
- ◆ Irrigated land was 18% of total crop land & produced 60% of market value!

Irrigation's Importance to Carbon Sequestration and Global Warming

Irrigated Cropping Replaces
Sparse Desert Vegetation with
Large Biomass & C Sequestration

53.2 M ac Irrigated in the U.S.

An aerial photograph of a vast agricultural landscape. The land is divided into large, irregular sections. Several prominent circular features are visible, which are likely center pivot irrigation systems. The colors of the fields vary, showing different crops or stages of growth, ranging from dark green to light yellow/brown. The overall pattern is a mix of straight lines and curved shapes.

Rain-Derived Models

USLE

Statistic Event-Based

RUSLE

Statistic Event-Based

WEPP

System Process-Based

Attempts to apply these models to irrigation have failed to accurately predict IIE & runoff/infiltration, especially from surface irrigation, especially from small application rates

Storm events are vastly different from irrigation

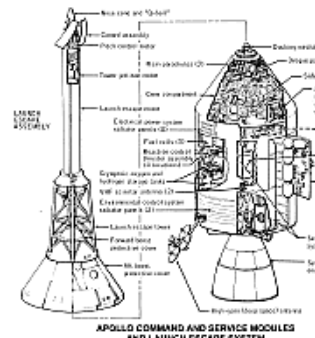

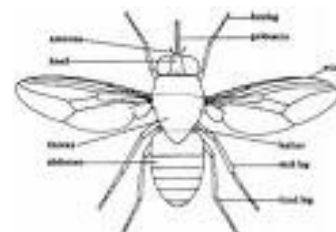

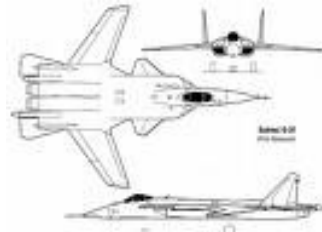

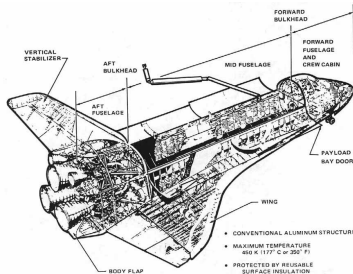

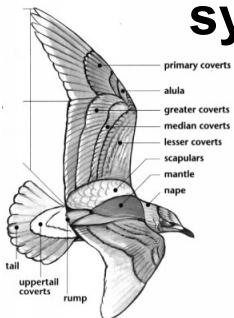

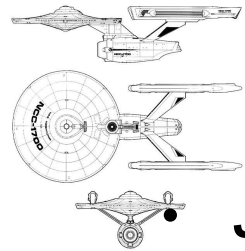

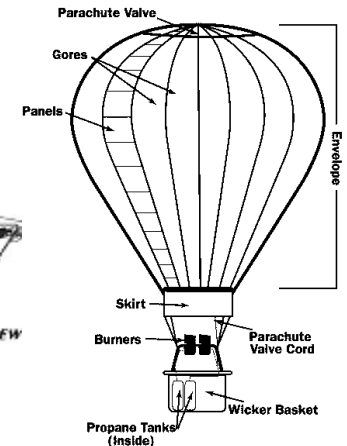

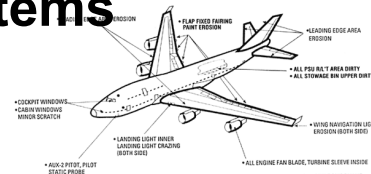

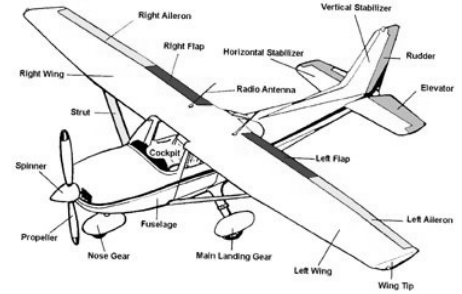

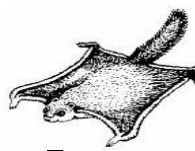

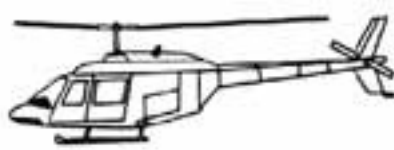

Process systematics differ between rain-induced and irrigation-induced erosion

Process Systematics Differ?

- Chemical & physical processes affecting erosion are the same
- Some processes are more/less prominent, with irrigation vs. rain thus components assemble into different systems

- Sequence & duration
- Spatial relationships
- Energy & mass balances (intensity)
- Component chemistries

Just as all means of flight draw from common chemical and physical processes, a single system model cannot easily describe all flight

**Erosion prediction is even more complicated
when erosion is driven by intermittent
irrigation and rainfall events—**

**-Especially if irrigation water quality
varies significantly from rainwater**

So... What's A Modeler To Do??

Ask Mark Nearing!!

Moving Forward with Irrigation Erosion Assessment Models

Furrow Irrigation – SISIM*

- **Current Surface-Irrigation Simulation Model is an empirical representation of furrow erosion rates:**
 - **$SISL = BSL * KA * PC * CP * IP$**
 - **BSL** Base soil loss (from 200 furrow irrigated fields, Idaho)
 - **KA** Soil Erodibility Adjustment factor
 - **PC** Prior Crop Adjustment factor
 - **CP** Conservation Practice Adjustment factor
 - **IP** Irrigation Management Adjustment factor

* Bjorneberg et al., 2007 – Evaluating the Surface Irrigation Simulation Model
Applied Eng. In Agriculture - IDAHO

Furrow Irrigation - SRFR *

- **Current Surface-Irrigation Simulation Model represents the basic processes needed to simulate furrow erosion, including:**
 - Numerical solution to unsteady flow equations with decreasing flow down-furrow
 - Selection of sediment transport equations to test
 - Physically-based detachment and deposition equations

* Strelkoff, T.S., and A.J. Clemmens. 2007. Hydraulics of Surface Systems. In: Design and Operation of Farm Irrigation Systems, ASABE.

Furrow Irrigation - SRFR

- **Needed work:**
 - **Ability to represent multiple size-classes of sediment, and thus preferential deposition and associated armoring**
 - **Further testing of sediment transport equations with multiple size-class sediment**
 - **Extensive collection of data of erosion for wide range of soils and water chemistry to develop parameter estimation equations**

Furrow Irrigation - SRFR

- **Also - Similar problems as with current rainfall erosion models:**
 - The sediment transport equations were developed for river-sized sediments
 - Head-cuts and furrow side-sloughing not explicitly represented

Sprinkler Irrigation

- Very little work has been done to advance sprinkler irrigation models
- Kincaid, 2002, conducted a WEPP application to sprinkler irrigation data from S. Idaho.
 - *“Soil loss predictions were unreliable for the small runoff amounts occurring in this study. The most reasonable use of WEPP for sprinkler irrigation would be for estimating when potential runoff might occur under center pivots for different soils, slopes, and crop management practices, and to determine limits on application depths and rates to avoid serious runoff.”*

Sprinkler Irrigation

- **Current erosion models (e.g., WEPP) use a spatially homogeneous rainfall input. Not designed to take sprinkler input, which is spatially heterogeneous and moves with time across the field.**
- **A spatially-explicit model must first be developed to represent spatially & temporally variable sprinkler water input -**
- **Followed by extensive data collection, testing and parameterization (soil, water, etc.)**

Thank You
