

Measuring DM and NDF Digestibility and Defining Their Importance

David R. Mertens

USDA-ARS

U.S. Dairy Forage Research Center

Presented at the 2002 NIRS
Consortium Meeting

Why do we measure digestibility

- Digestibility is important because feces represent the greatest loss of ingested energy
 - Feces = 20-50% loss of energy (DE)
 - Gasses + Urine = 15-25% loss of energy (ME)
 - Heat = 5-15% loss of energy (NE)
- Uses (value) of measuring digestibility
 - As an indicator of feed nutritive value
 - As a predictor of animal performance

Digestibility as a Measure of Animal Performance

- Want to maximize the accuracy of measuring animal performance
 - Lab results must mimic field performance
 - Animal and diet must match field conditions
- Animal differences are an integral part of the measurement
 - Performance is determined by both feed and animal characteristics
 - Want to duplicate actual performance

Digestibility as a Measure of Animal Performance

- In vivo production digestibility protocol
 - Performance status of animals
 - Production level of intake (1-5X Mnt)
 - Ad libitum (free choice) intake with refusals = selection
 - Measures digestibility during production
 - Much greater variability = difficult to measure inputs and outputs

Digestibility as a Measure of Feed Nutritive Value

- Want to maximize the accuracy and precision of measuring feed's nutritive value
 - Must be repeatable within labs
 - Must be reproducible among labs
- Must minimize animal differences (within and among labs)
 - Animals are the measuring device
 - Want to measure feed, not animal differences

Digestibility as a Measure of Feed Nutritive Value

- Standardized in vivo digestibility protocol
 - Mature animals
 - Maintenance level of intake (1X Mnt)
 - No selection or refusals
 - Measures maximum digestibility
 - Weigh feed, refusals and feces for 5-7 days

In Vivo Digestibility

- Is a biological evaluation of a feed
- Is not a constant, but varies with
 - Species
 - Size
 - Production level
 - Intake
 - Selection and sorting
 - Methodology

In Situ / In Sacco Digestibility

- Is a biological evaluation of a feed
- Feed is sealed in a porous bag and suspended in the rumen of fistulated COWS
- Assume in situ = in vivo
 - But only measures fermentative digestion
 - Not adequate for low fiber feeds
 - Losses from the bag may compensate for the lack of intestinal digestion

In Situ / In Sacco Digestibility

- Apparent value is in mimicking ruminal digestion for production levels and diets
- More difficult to standardize, especially among labs when used for feed evaluation
 - Bag dimensions and pore sizes
 - Washing of bags and removal of fines
 - Cyclic and variable ruminal conditions
 - Variability among animals

In Vitro Digestibility

- **Single-stage IVDMD**
 - Incubate ruminal fluid with feed in buffer
 - Dry residues and weigh
- **Two-stage Tilley & Terry IVDMD**
 - Incubate ruminal fluid with feed in buffer
 - Incubate undigested residue in acid pepsin
 - Dry residues and weigh

In Vitro Digestibility

Two-stage Van Soest IVDMTD

- Incubate ruminal fluid with feed in buffer
- Extract undigested residue in neutral detergent
- Dry NDF residues and weigh
- **In vitro methods measure different things**
 - Single and two-stage T&T IV measure apparent DM digestibility
 - Two-stage Van Soest IV measures true DM digestibility

In Vitro Digestibility

Two-stage T&T IVDMD

- 48 hr fermentation highly correlated with in vivo DMD at 1xMaintenance
- DOES NOT mean that IVDMD = in vivo DMD
- Will be lower value than 2-stage VS IVDMTD because undigested residues contain microbial debris (part of in vivo endogenous loss)

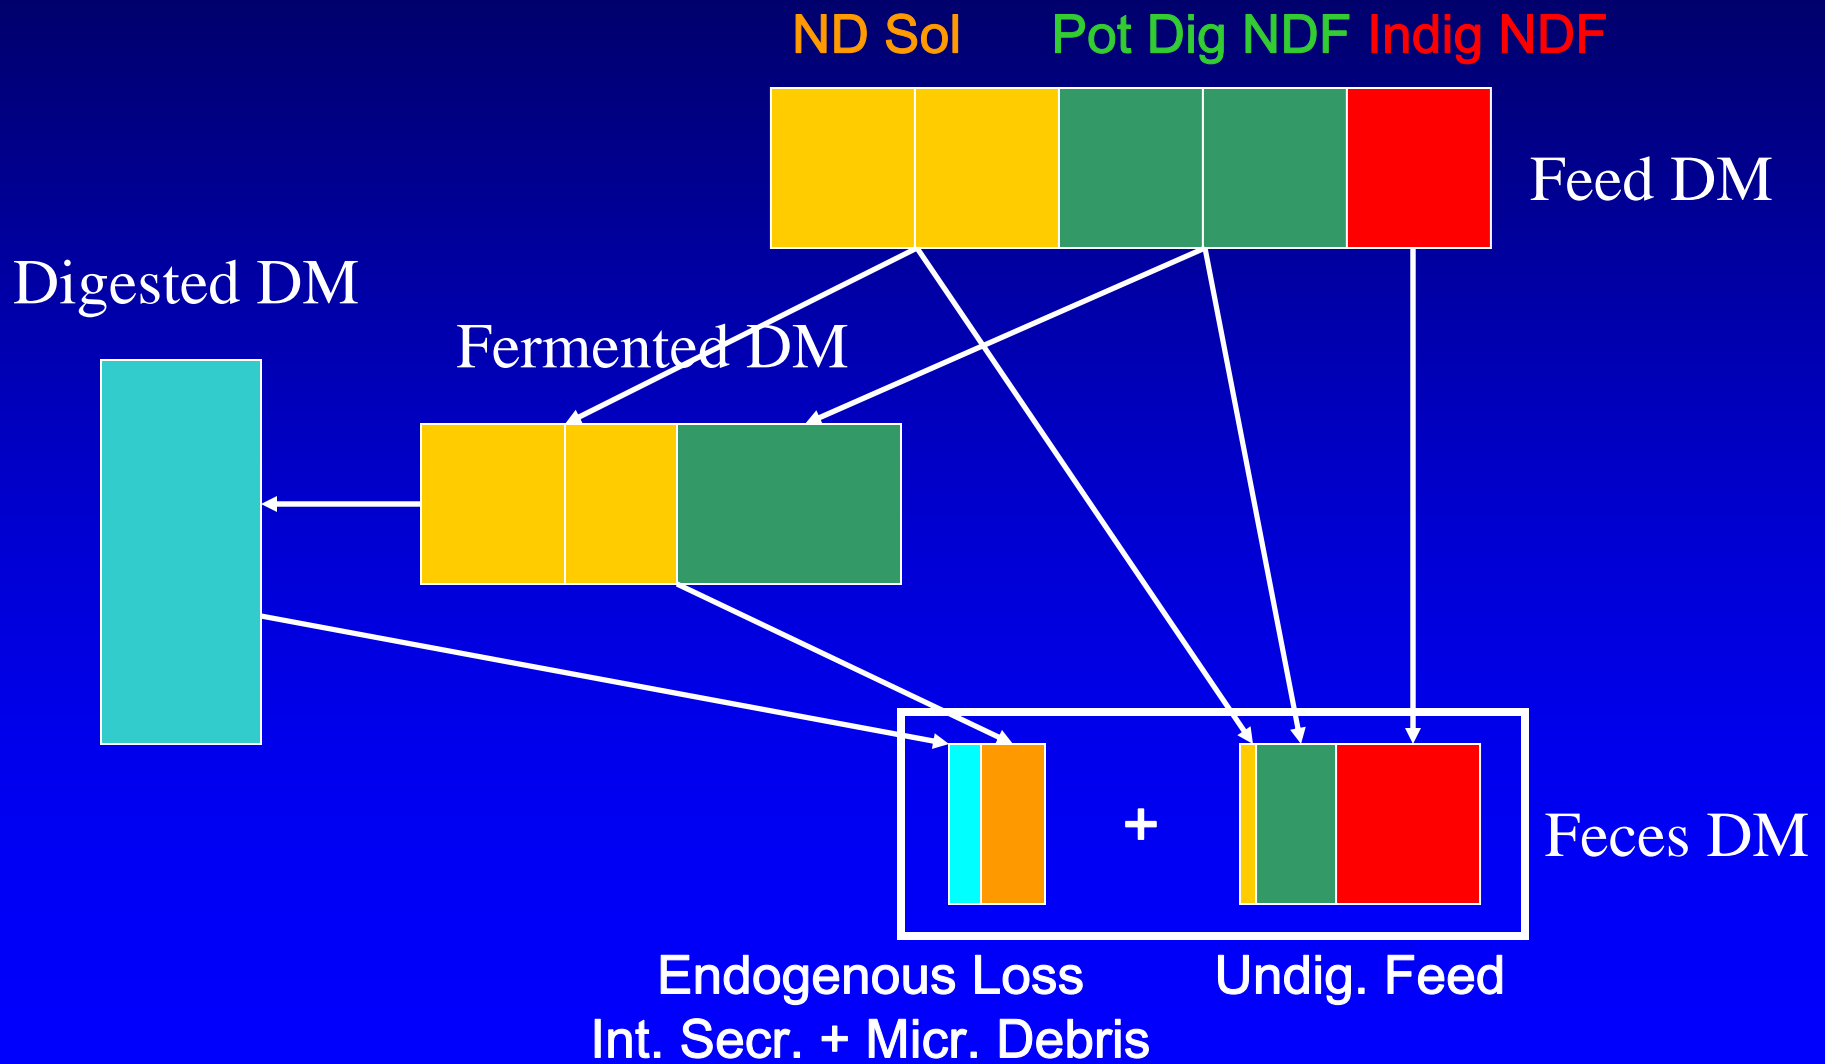

In Vitro Gas Production and Digestibility

- Usually a closed system
 - Buffers do not work well and pH drops after 12-24 hr
- Used to measure fermentation curves
 - Assume that production of fermentation gas is proportional to DM disappearance

In Vitro Fermentation Time versus In Vivo Retention Time

- In vivo Retention Time DOES NOT equal in vitro fermentation time
 - i.e., digestion at 30 hr retention time DOES NOT digestion at 30 hr fermentation time
 - In vivo digestion = $k_d / (k_d + k_p)$
 - In vitro digestion = $1 - DM \cdot \exp(-k \cdot t)$

Apparent versus True Digestibility

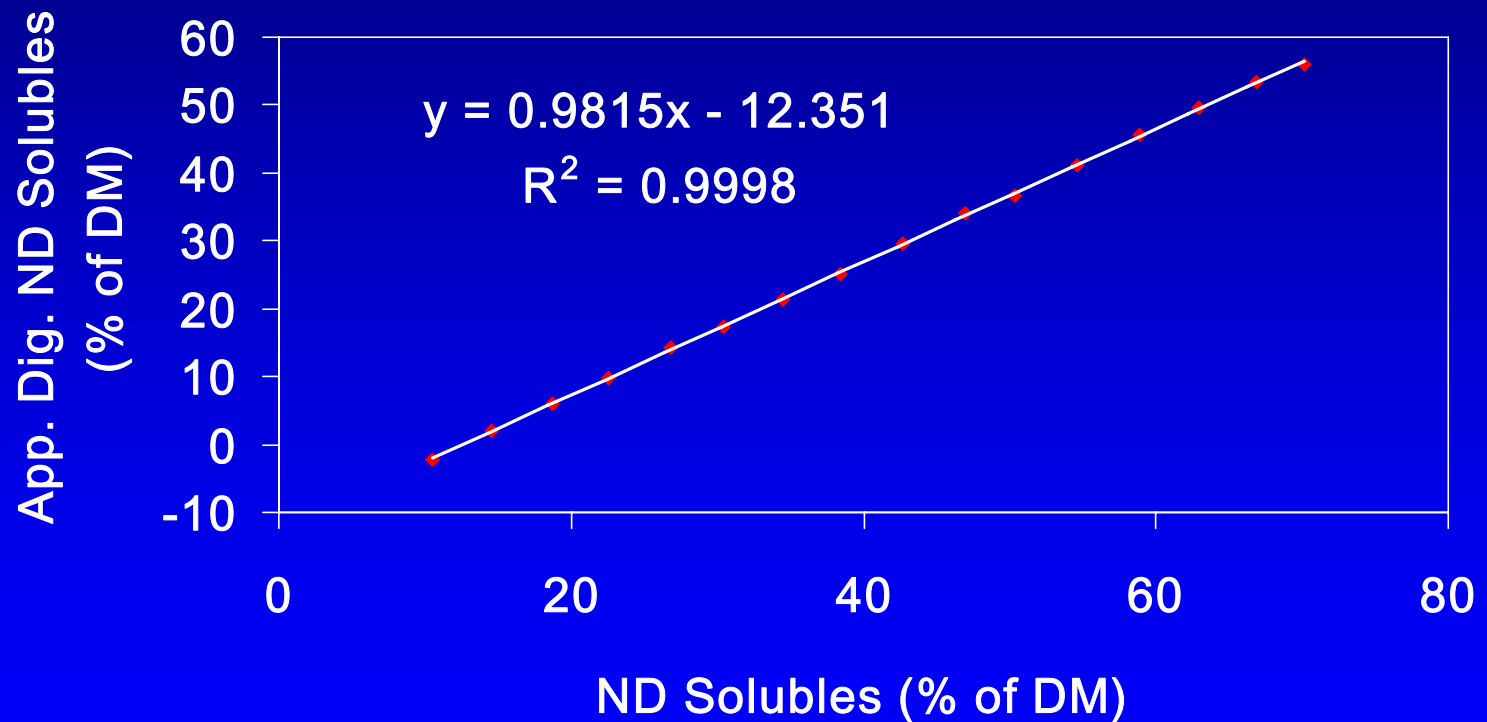

Apparent versus True Digestibility

- Apparent DM digestibility (% DMD) =
– $100 * [\text{Feed DM} - \text{Fecal DM}] / (\text{Feed DM})$
- DM true digestibility (% DMTD) =
– $100 * [\text{Feed DM} - \text{Undig Feed DM}] / (\text{Feed DM})$
- $\text{DMTD} > \text{DMD}$, e.g., 78% vs 65%

Apparent versus True Digestibility

- Measuring true digestibility is difficult because there are limited ways of estimating or measuring endogenous losses
 - Regression for ideal nutritive entities
 - Have constant slope (estimates true dig.)
 - Have constant intercept (estimates End. Loss)
 - Analytically remove endogenous losses from feces using neutral detergent

Using Regression to Estimate True Digestibility and Endogenous Loss

Ideal Nutritive Entities

- Have constant slope (true dig) near 0 or 1
- Have a negative intercept = endogenous loss
- Include
 - dCP = $-3.5 + 0.95*CP$
 - dEE = $-1.5 + 0.98*EE$
 - dSolCHO ? = $-2.0 + 1.00*SolCHO$
 - dNDS = $-12.9 + 0.98*NDS$

Summative Equations for Calculating Digestibility

- Based on the concept of Ideal Nutritive Entities
 - Identify them
 - Determine their true digestibilities and endogenous losses
 - Sum them
- Largest Ideal Nutritive Entity is Neutral Detergent Solubles
- Other Ideal Nutritive Entities are CP, EE, Sugars, Soluble Carbohydrates, & Lignin

Summative Equations for Calculating Digestibility

- Largest Ideal Nutritive Entity is Neutral Detergent Solubles ($NDS = 100 - NDF$)
 - True Digestibility = 0.98
 - Endogenous Loss = -12.9
 - $dNDS = -12.9 + 0.98 * NDS$
- Remaining fraction (NDF) is not ideal and its digestibility must be determined
 - $dNDF = NDFD * NDF$
- $dDM = DMD = dNDS + dNDF$

Summative Equations for Calculating Digestibility

- $VS\ DMD = 0.98 * NDS + NDFD * NDF - 12.9$
- Dairy NRC (2001) and Milk2000 are an expansion of the VS summative equation
- NRC2001 calculated Total Digestible Nutrients (TDN) by subdividing NDS
 - $TDN_{1x} = tdCP + tdFA * 2.25 + tdNFC + tdNDF - 7$
 - $FA = (EE - 1)$, $NFC = 100 - (NDF - NDF_{ICP}) - CP - EE - Ash$, $CPTD = \exp(-1.2 * ADICP / CP)$, $FATD = 1.0$, $NFCTD = 0.98 * PAF$ and $tdNDF = 0.75 * (NDF - NDF_{ICP} - Lignin) * [1 - (Lignin / NDF)^{2/3}]$ or $?? * IVNDFD * NDF$

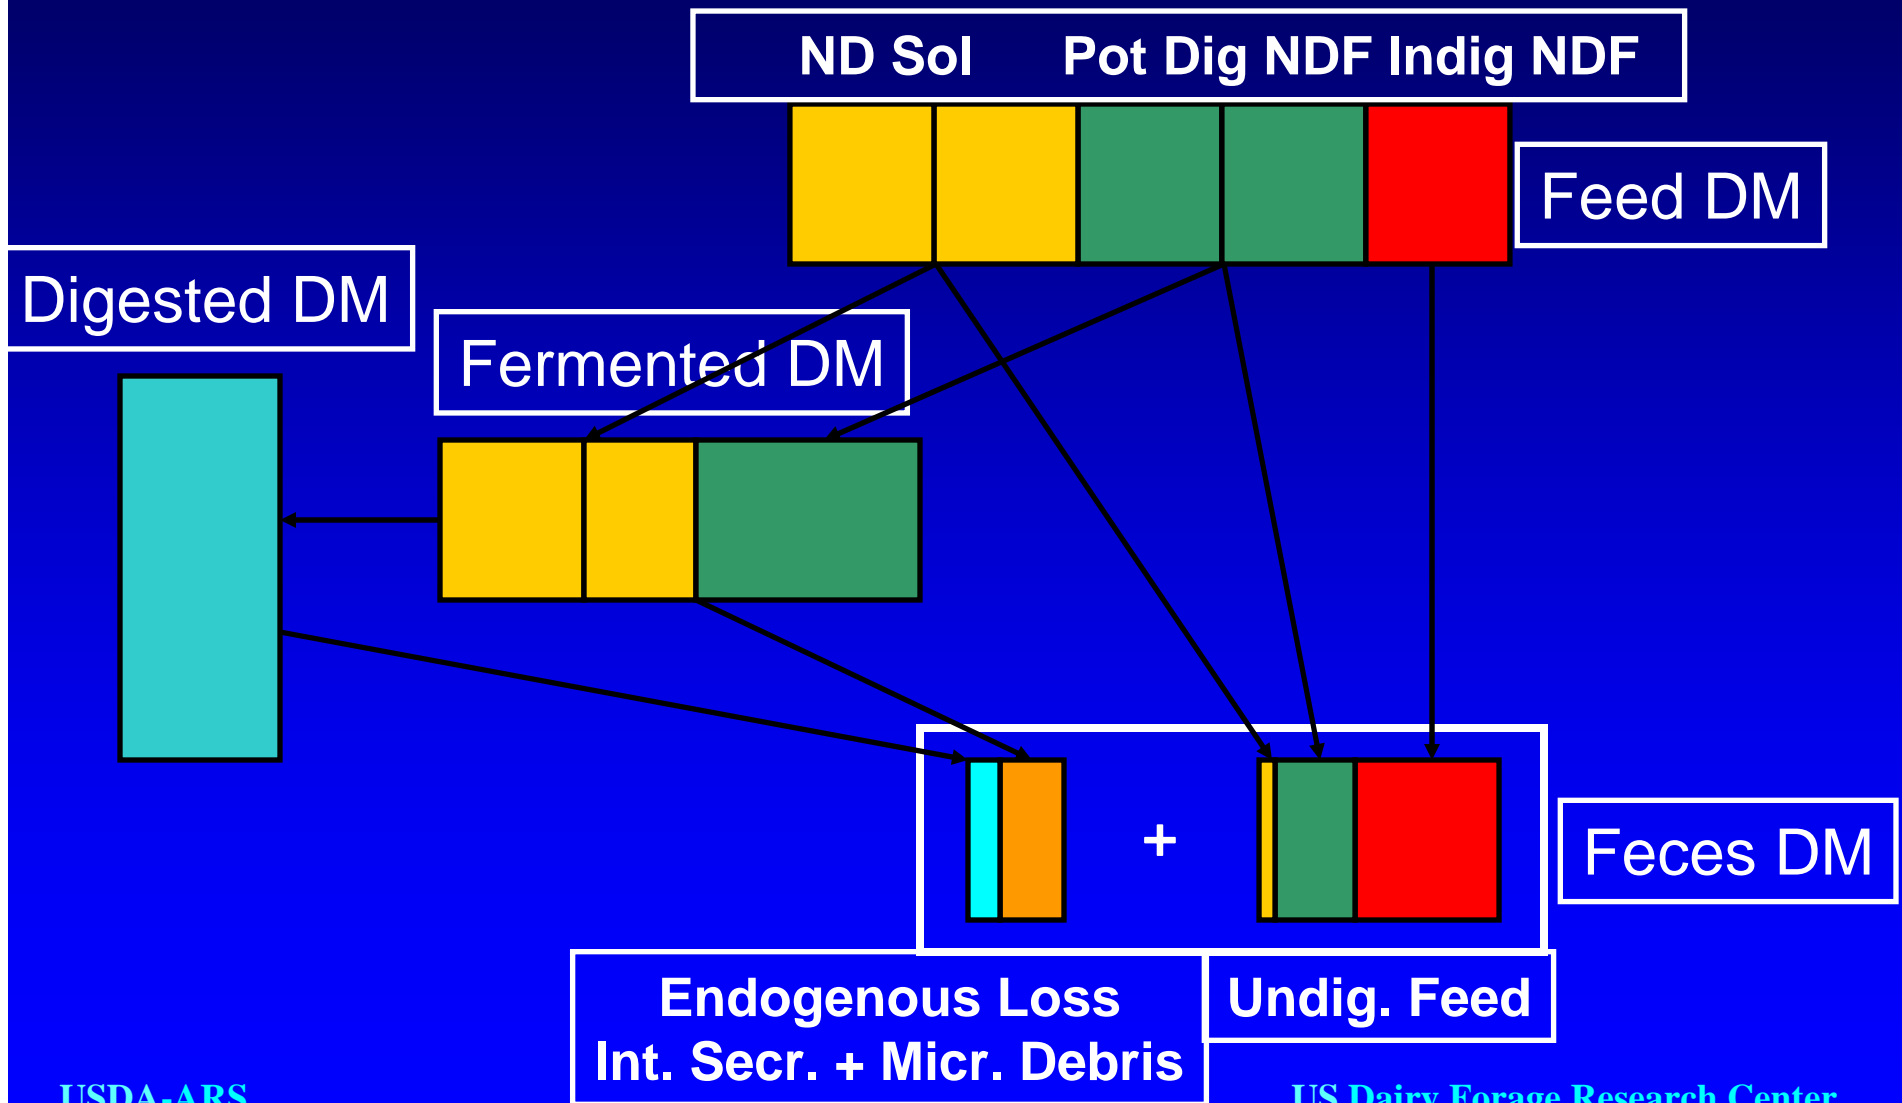

Summative Equations for Calculating Digestibility

- Milk2000 equation indicates that Starch is not an Ideal Nutritive Entity and removes it from NFC
 - $\text{TDN}_{1x} = \text{tdCP} + \text{tdFA} + \text{tdNSNFC} + \text{tdST} + \text{tdNDF} - 7$
 - Non-starch NFC (NSNFC) = (NFC – Starch) has a variable Starch Digestibility depending on corn silage %DM and processing

Summative vs Empirical Equations

- Empirical equations assume that the true digestibility of fiber is constant (or correlated with fiber content)
 - Works best for ADF vs NDF because ADF contains a higher proportion of lignin and indigestible residues
- Summative allows NDFD to vary
 - $DMD = .98 * NDS + NDFD * NDF - 12.9$
 - $= .98 * (100 - NDF) + NDFD * NDF - 12.9$
 - $= (98 - 12.9) - (98 - NDFD) * (NDF)$

Apparent versus True Digestibility

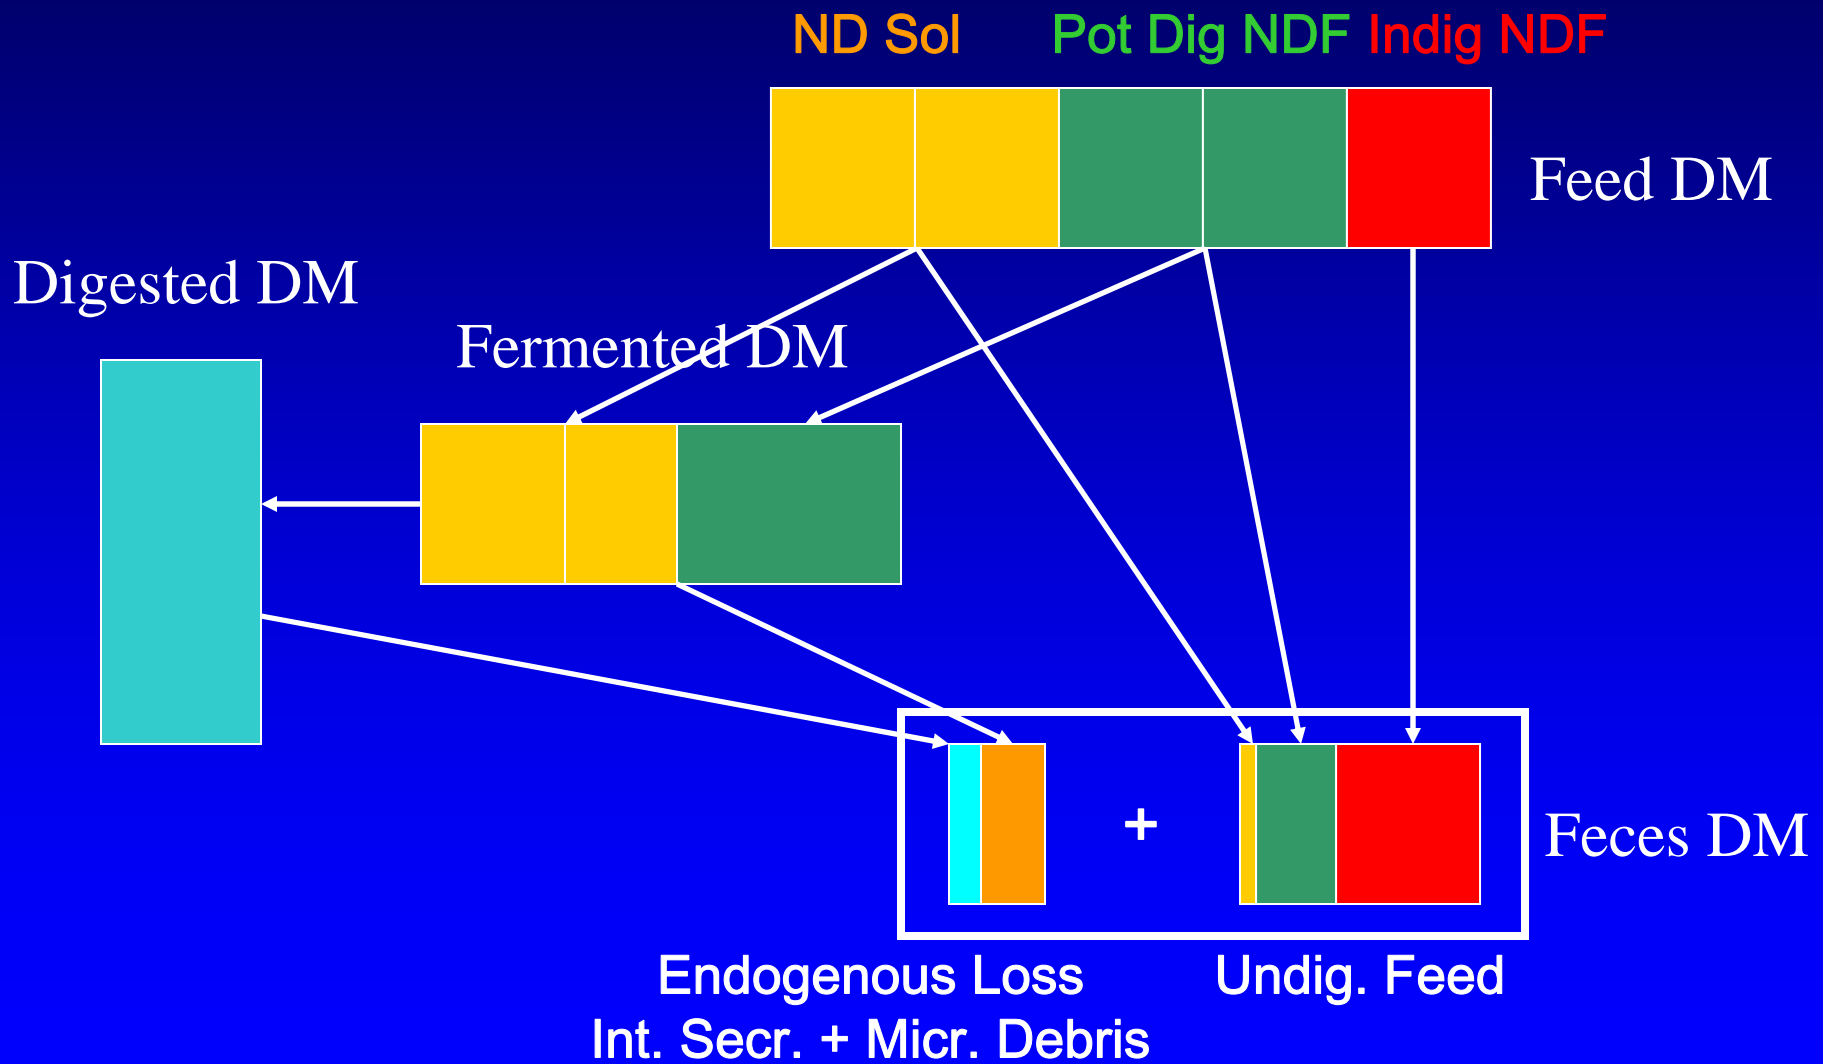

Use Neutral Detergent to Remove Endogenous Losses from Feces

- ND will dissolve intestinal secretions
- ND will dissolve microbial debris
- But ND also dissolves undigested solubles
 - Only a problem in starchy feeds when starch is poorly digested, e.g, undamaged or coarsely cracked mature corn grain

Use Neutral Detergent to Remove Endogenous Losses from Feces

- In most feeds undigested feed in feeds is primarily fiber (aNDF)
- Procedure is to extract feces with ND to remove endogenous losses and recover undigested feed
- $\% \text{ DMTD} = 100 * [\text{Feed DM} - (\text{ND extracted fecal DM})] / \text{Feed DM}$

Apparent versus True Digestibility

Digestible Nutrient vs Nutrient Digestibility

- Nutrient Digestibility IS NOT the same as digestible Nutrient – UNITS ARE IMPORTANT
- Nutrient digestibility is always expressed as a percentage of the nutrient, i.e., it is the fraction of the nutrient that is digested, a digestion coefficient
- digestible Nutrient is always expressed as a percentage of the feed DM, i.e., it is the fraction of feed DM that is digested nutrient

Digestible Nutrient vs Nutrient Digestibility

- To distinguish between them I suggest the following terminology and abbreviations
 - dNut = digestible nutrient = % of digested nutrient in feed DM
 - NutD = nutrient Digestibility = % of nutrient that is digested
- DM is an exception, dDM = DMD because digestible DM is expressed per unit of itself

Digestible Nutrient vs Nutrient Digestibility

- Example:

- Cow eats 50 lb of feed containing 20% CP and excretes 15 lb of feces containing 15% CP

- $\%CPD = 100 * (\text{Feed CP} - \text{Fecal CP}) / \text{Feed CP}$

- $\text{Feed CP} = 50 * 20/100 = 10 \text{ lb CP}$

- $\text{Fecal CP} = 15 * 15/100 = 2.25 \text{ lb CP}$

- $\%CPD = 100 * (10 - 2.25) / 10 = 77.5\%$

Digestible Nutrient vs Nutrient Digestibility

- Example:

- digestible CP is always expressed in % of DM
- $dCP = 100 * (\text{Feed CP} - \text{Fecal CP}) / \text{Feed DM}$
- $dCP = 100 * (10 - 2.25) \text{ lbs CP} / 50 \text{ lb Feed DM}$
- $dCP = 15.5\%$ of DM
- $dCP = CP * CPD/100 = 20 * 77.5/100 = 15.5\%$ of DM

dNDF versus NDFD

- dNDF is better than NDFD (Mertens' opinion)
 - dNDF=(100-iNDF) are actually measured in vitro
 - dNDF is actually used to calculate DMD
- $dNDF = NDF * (NDFD/100)$
 - NDFD separates the affect from NDF
- iNDF (and dNDF) related to Lignin as % of DM
- NDFD related to Lignin as % of NDF

dNDF & NDFD Equations

- Procedure:
 - Determine NDF of the original samples (**NDF, %DM**);
 - Run ~0.5 g (DMwt, g) IV for 48h, followed by a NDF (**NDFres, g**);
- $IVDMTD = 100 * [DMwt - NDFres) / DMwt]$; (%DM)
- $iNDF = 100 - IVDMTD$; (%DM)
- $dNDF = NDF - iNDF$; (%DM)
- $NDFD = 100 * dNDF / NDF$; (%NDF)
- $= 100 * [NDF - (100 - IVDMTD)] / NDF$

dNDF & NDFD Equations

- Example:
 - NDF = 50 %DM
 - Sample DMwt = 0.5 g
 - NDFres = 0.1 g
- $IVDMTD = 100 * [(0.5 - 0.1) / 0.5]; = 80\% \text{ DM}$
- $iNDF = 100 - 80 = 20\% \text{ DM}$
- $dNDF = 50 - 20 = 30\% \text{ DM}$
- $NDFD = 100 * (30 / 50) = 60\% \text{ NDF}$

Calculating IVDMTD and IVNDFD

	Rep1	Rep2	Rep3	Rep4	Avg	SD
Sample wt	0.51	0.505	0.495	0.5

Conclusions

- Digestion is important
- Digestibility measurements are a function of method
- Know which IV method is used
 - Important for IVDMTD vs IVDMD
 - Only one way to measure NDFD
- dNDF is more important than NDFD (Mertens' opinion)
- NDFD may have high SD and we may not be able to discriminate other than High, Medium and Low
